TEMPCO Model PCM10024 Portable Control Console
Instruction Manual

SPECIFICATIONS

Control Zones: 1
Temperature Controller: Model TEC-9100, 1/16 DIN PID Time Proportioning
Sensor Input: ANSI Type “J” Thermocouple
Power Cord Input: 120 VAC, 50-60 Hz
Heater Output: 120 VAC — 16 amps maximum (1,920 watts maximum)
Output Device: Mechanical Relay
Main Power Switch: Located on front panel
Main Power Fuse: Buss ABC-20-R (located on back panel)
Control Power Fuse: Buss ABC-1 (located on back panel)

WARNINGS

1. Dangerous voltage capable of causing injury or death is present within this console. Power to all
equipment must be disconnected before installation or beginning any troubleshooting procedures.

   Heater output wiring and component replacement
   must be made by qualified personnel only.

2. To minimize the possibility of fire or shock, do not expose this console to rain or excessive moisture.

3. Do not use this console in areas where hazardous conditions exist such as excessive shock,
vibration, dirt, corrosive gases, oil or where explosive gases or vapors are present.

WIRING  (For safety, disconnect all power sources prior to wiring)

1. Attach the leads from your type “J” thermocouple to the black mini-plug provided. Take care to
note the correct polarity. For a type “J” thermocouple, the white lead is (+) positive and the red lead
is (-) negative.

2. The heater output current is sourced directly through the 120V line cord. The rear console output
receptacle provides live controlled power for direct connection to your heater(s). Connect one lead
from your heater to one prong of the Hubbell plug (not ground). Connect the other lead from your heater
to the other prong. Connect heater ground (if applicable) to the ground connection (G) on the plug.
OPERATION

1. Verify the power switch is in the off position. Plug in your thermocouple and heater load. Plug the provided 120 V line cord from the console into a 20 Amp, Grounded 120 VAC outlet. Switch on the PCM10024.

2. Set your desired temperature setpoint by using the up and down arrow buttons on the TEC-9100 temperature controller.

3. Refer to the Instruction Manual provided for complete operation and auto-tuning of the TEC-9100 temperature controller.

4. The standard PCM console is set to control electric heaters and cycle the heaters on and off to maintain an accurate temperature. The TEC-9100 controller can easily be changed to “on-off” action which eliminates this cycling, such as for the control of solenoid valves. To accomplish this, go to the “Pb” setting and lower that to zero. Then go to the “HYST” setting and the number you enter there will become the hysteresis (deadband) setting.

1–3 Programming Port

The TEC99011 cable and TEC99003 network adapter can be used to connect the programming port to a PC for automatic configuration. The programming port is used for offline automatic setup and testing procedures only. Don't attempt to make any connection to these pins when the unit is used for a normal control purpose.

1–4 Keys and Displays

KEYPAD OPERATION

SCROLL KEY:<br>This key is used to select a parameter to be viewed or adjusted.

UP KEY:<br>This key is used to increase the value of the selected parameter.

DOWN KEY:<br>This key is used to decrease the value of the selected parameter.

RESET KEY:<br>This key is used to:
1. Revert the display to show the process value.
2. Reset the latching alarm, once the alarm condition is removed.
3. Stop the manual control mode, auto-tuning mode, and calibration mode.
4. Clear the message of communication error and auto-tuning error.
5. Restart the dwell timer when the dwell timer has timed out.
6. Enter the manual control menu when in failure mode.

ENTER KEY: Press for 5 seconds or longer.
Press for 5 seconds to:
1. Enter setup menu. The display shows .
2. Enter manual control mode—when manual control mode is selected.
3. Enter auto-tuning mode—when auto-tuning mode is selected.
4. Perform calibration to a selected parameter during the calibration procedure.
   Press for 6.2 seconds to select manual control mode.
   Press for 7.4 seconds to select auto-tuning mode.
   Press for 8.6 seconds to select calibration mode.

Figure 1.4 Display during Power Up

Display program code of the product for 2.5 seconds.
The left diagram shows program number 6 for TEC-9100 with version 12.
Entering these modes will break the control loop and change some of the previously set data. Make sure that the system is able to accept these modes.

*1: This flow chart shows a complete listing of all parameters. For actual application, the number of available parameters depends on setup conditions and could be less than that shown in the flow chart.

*2: You can select up to 8 parameters to be placed in the user menu by using SEL1–SEL8 located at the bottom of setup menu.

*3: Release [1], press [1] again for at least 2 but no more than 3 seconds, then release to access the calibration menu.

The user menu shown in the flow chart corresponds to the default setting for SELECT parameters SEL1 to SEL8. SP3 will be hidden if NONE is selected for ALFN. SP2 will be hidden if the alarm function is not selected for OUT2. An unused parameter will be hidden even if it selected by the SEL parameters.

*Controller Parameter Descriptions that are not applicable are not shown in the above table.*
Control Outputs

**Heat only ON-OFF control:** Select REVR for OUT1. Set PB (proportional band) to 0. O1HY is used to adjust dead band for ON-OFF control. The output 1 hysteresis (O1HY) is enabled in case PB=0. The heat only on-off control function is shown in the following diagram:

![Heat Only ON-OFF Control Diagram](image)

**OFST function:** OFST is measured by % with a range of 0–100.0%. In the steady state (i.e., process has been stabilized), if the process value is lower than the set point by a definite value, say 5°C, while 20°C is used for PB, that is lower by 25%, then increase OFST 25%, and vice-versa. After adjusting OFST value, the process value will be varied and eventually coincide with set point.

Refer to section 3-12 “manual tuning” for the adjustment of PB and TD. Manual reset (adjust OFST) is not practical because the load may change from time to time and OFST may need to be adjusted repeatedly. PID control can avoid this situation.

**Heat only PID control:** If REVR is selected for OUT1, PB and TI should not be zero. Perform auto-tuning for the new process, or set PB, TI, and TD with historical values. See section 3-11 for auto-tuning operation. If the control result is still unsatisfactory, then use manual tuning to improve control. See section 3-12 for manual tuning. The unit contains a very advanced PID and Fuzzy Logic algorithm to create a very small overshoot and very quick response to the process if it is properly tuned.

**Cool only control:** ON-OFF control, P (PD) control, and PID control can be used for cool control. Set OUT1 to DIRT (direct action). The other functions for cool only ON-OFF control, cool only P (PD) control, and cool only PID control are the same as for heat only control except that the output variable (and action) for cool control is inverse to heat control.

**Note:** ON-OFF control may result in excessive overshoot and undershoot problems in the process. P (or PD) control will result in a deviation of process value from the set point. It is recommended to use PID control for heat-cool control to produce a stable and zero offset process value.

![Ramp Function Diagram](image)

**Ramp**

The ramping function is performed during power up as well as any time the set point is changed. If MINR or HRR is chosen for RAMP, the unit will perform the ramping function. The ramp rate is programmed by adjusting RR. The ramping function is disabled as soon as failure mode, manual control mode, auto-tuning mode or calibration mode is entered.

**Example without dwell timer**

Select MINR for RAMP, select °C for UNIT, select 1-DP for DP, set RR=10.0. SV is set to 200°C initially, and changed to 100°C 30 minutes after power-up. The starting temperature is 30°C. After power-up, the process runs like the curve shown below:

![RAMP Function Curve](image)

**Note:** When the ramp function is used, the lower display will show the current ramping value. The ramping value is an artificially determined setpoint created and updated by the control to match the ramp rate set by the user. However, it will revert to show the set point value as soon as the up or down key is touched for adjustment. The ramping value is initiated to process value either on power-up or when RR and/or the set point are changed. Setting RR to zero means no ramp function.
PV Shift

In certain applications it is desirable to shift the controller display value (PV) from its actual value. This can easily be accomplished by using the PV shift function.

The SHIF function will alter PV only.

Example: A process is equipped with a heater, a sensor, and a subject to be warmed up. Due to the design and position of the components in the system, the sensor could not be placed any closer to the part. Thermal gradient (differing temperatures) is common and necessary to an extent in any thermal system for heat to be transferred from one point to another. If the difference between the sensor and the subject is 35°C, and the desired temperature at the subject to be heated is 200°C, the temperature at the sensor should be 235°C. You should enter -35°C to subtract 35°C from the actual process display. This in turn will cause the controller to energize the load and bring the process display up to the set point value.

Failure Transfer

The controller will enter failure mode if one of the following conditions occurs:

1. **SBER** occurs due to input sensor break or input current below 1mA if 4–20 mA is selected or input voltage below 0.25V if 1–5V is selected.
2. **ADER** occurs due to the A-D converter of the controller failing.

Output 1 and output 2 will perform the failure transfer function as the controller enters failure mode.

### Output 1 failure transfer, if activated, will perform:

1. If output 1 is configured as proportional control (PB≠ 0), and BPLS is selected for O1FT, then output 1 will perform bumpless transfer. Thereafter, the previous averaging value of MV1 will be used for controlling output 1.
2. If output 1 is configured as proportional control (PB≠ 0), and a value of 0 to 100.0% is set for O1FT, then output 1 will perform failure transfer. Thereafter, the value of O1FT will be used for controlling output 1.
3. If output 1 is configured as ON-OFF control (PB=0), then output 1 will be driven OFF if OFF is set for O1FT and will be driven ON if ON is set for O1FT.

Manual Control

Operation

To enable manual control, the LOCK parameter should be set to NONE, then press for 6.2 seconds; (hand control) will appear on the display. Press for 5 seconds, then the MAN indicator will begin to flash and the lower display will show . The controller is now in manual control mode. indicates output control variable for output 1, and indicates control variable for output 2. Now you can use the up and down keys to adjust the percentage values for the heating or cooling output.

The controller performs open loop control as long as it stays in manual control mode.

Exit Manual Control

Pressing the key will cause the controller to revert to its normal display mode.
Auto-tuning

The auto-tuning process is performed near the set point. The process will oscillate around the set point during the tuning process. Set the set point at a lower value if overshooting beyond the normal process value is likely to cause damage.

Auto-tuning is applied in cases of:

- **Initial setup for a new process**
- **The set point is changed substantially from the previous auto-tuning value**
- **The control result is unsatisfactory**

**Operation:**

1. The system has been installed normally.
2. Set the correct values for the setup menu of the unit, but don’t set a zero value for PB and TI, or the auto-tuning program will be disabled. The LOCK parameter should be set at NONE.
3. Set the set point to a normal operating value, or a lower value if overshooting beyond the normal process value is likely to cause damage.
4. Press and hold until appears on the display.
5. Then press again for at least 5 seconds. The AT indicator will begin to flash and the auto-tuning procedure begins.

**NOTE:** The ramping function, if used, will be disabled when auto-tuning is taking place.

Auto-tuning mode is disabled as soon as either failure mode or manual control mode is entered.

**Procedures:**

Auto-tuning can be applied either as the process is warming up (cold start), or when the process has been in a steady state (warm start). After the auto-tuning procedures are completed, the AT indicator will cease to flash and the unit will revert to PID control using its new PID values. The PID values obtained are stored in the nonvolatile memory.

**Auto-Tuning Error**

If auto-tuning fails an ATER message will appear on the upper display in the following cases:

- If PB exceeds 9000 (9000 PU, 900.0°F or 500.0°C),
- if TI exceeds 1000 seconds,
- if the set point is changed during the auto-tuning procedure.

**Solutions to Auto-Tuning Error**

1. Try auto-tuning once again.
2. Don’t change the set point value during the auto-tuning procedure.
3. Don’t set a zero value for PB and TI.
4. Use manual tuning instead of auto-tuning (see section 3-12).
5. Touch RESET key to reset message.

**Manual Tuning**

In certain applications auto-tuning may be inadequate for the control requirements. You can try manual tuning for these applications.

If the control performance using auto-tuning is still unsatisfactory, the following rules can be applied for further adjustment of PID values:

<table>
<thead>
<tr>
